COVER LETTER

Dear Ms. Doe,

Your sample for the analysis arrived on in the laboratory and was evaluated according to the highest laboratory quality standards. The results were evaluated and released by two independent geneticists and molecular biologists. After obtaining the results, your personal report was compiled. We hereby convey the results to you in the format of your choice.

We would like to thank you for your trust and hope that you are satisfied with our service. We are always open to questions and suggestions. Please do not hesitate to contact us. We value your feedback. This is the only way we can continuously improve our services.

We hope the analysis meets your expectations.

Kind regards,

Dr. Daniel Wallerstorfer BSc.
Laboratory Director

Florian Schneebauer, MSc.
Laboratory Manager

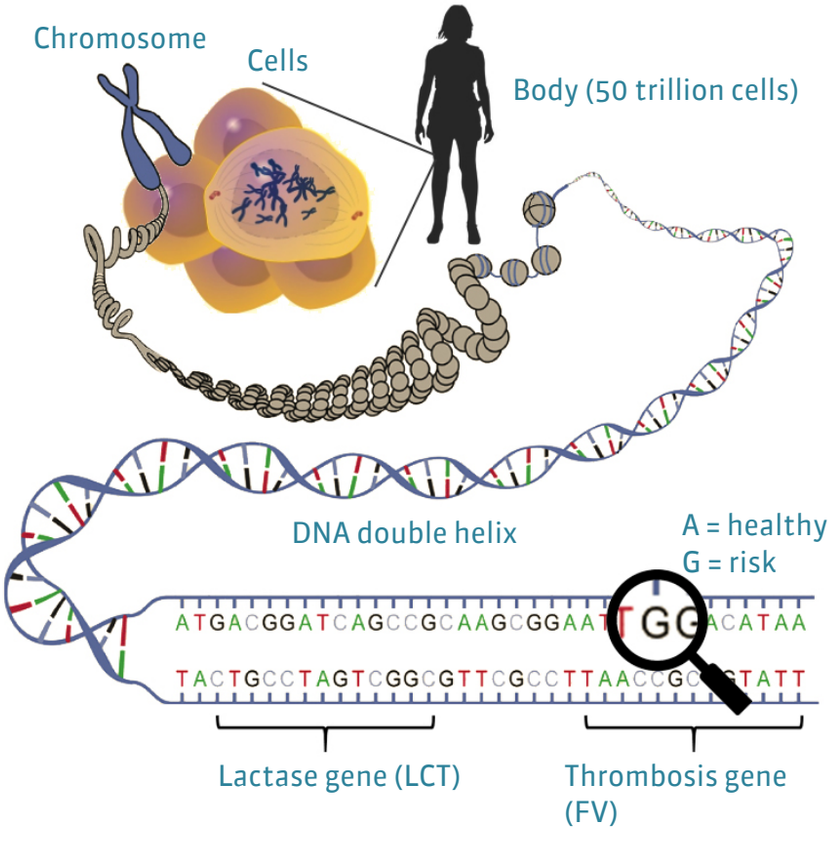
How genes influence our health

The human body consists of about 50 trillion individual cells. Most of these cells have a nucleus, which contains 46 chromosomes. A chromosome consists of a very closely wound thread, the DNA "double helix."



DNA, the genetic code, is the blueprint of the human body. This genetic code consists of approximately 3.1 billion molecules, which are each represented by a letter. About 1% of this code makes up the genes. Each gene is an instruction for the body, usually with a single function. For example, some genes tell the body how to colour the iris and differences in these genes produce different eye colors. Every function of the body is controlled by one or more genes, including the way we break down food or medication.

Our genes are not completely error-free. The genes of each person are altered slightly by environmental effects. Most of these changes have no effect but a small number have a harmful effect. An even tinier number can produce a beneficial effect. Parents pass these changes, including defects, to their children. Thus most of our genetic defects are inherited from our parents.

In addition, our genes evolved to help us live in a completely different world, and some of our genetic traits can interact with our modern environment to create negative effects on the body. For example, the genetic predisposition to store dietary fat quickly and lose it slowly is beneficial for people who go through times when food is scarce: they have a better chance of surviving because their bodies use fat efficiently and store it for later. However, in the modern world, this trait is harmful because it programs the body to gain weight quickly and lose weight

slowly. Genes increase our risk of heart attacks, trigger asthma and allergies, cause lactose intolerance, and many other disorders.

Genetic traits can affect our health. While some genetic defects cause disease in all cases, most genetic traits just increase our risk of developing a disease. For example, a person may have genes that increase their risk for diabetes. However, not everyone at risk for diabetes actually develops the disease. Furthermore, even people with a high risk of diabetes can lower their risk with the right diet and exercise plan. Other genetic traits only cause illness when they are triggered by a specific environmental feature. For example, lactose intolerance is a genetic condition that causes a person who drinks milk to have digestive issues. A lactose-intolerant person who never drinks milk will not have any symptoms.

Thanks to the latest technologies, it is now possible to test specific genes to determine if you have genetic traits that are linked to various diseases. Based on the results of the analysis, we can develop a prevention program that significantly reduces your personal disease risk and helps you stay healthy.

A healthy lifestyle will decrease your risk of many diseases whether or not you have specific information about your genetic traits. However, we provide you with additional information that may point out other changes to your lifestyle that are not part of the standard medical advice. There are many examples, but one of the traits we test for is a gene that increases your body's ability to absorb iron. If you have this trait, you must not take iron supplements as the iron would accumulate and cause a life-threatening disease called haemochromatosis.

Experts estimate that every person carries about 2,000 genetic defects, which may affect their health, and in some cases, cause illnesses. A variety of factors can cause changes in our genes (also called mutations). In a few cases, these mutations can benefit us. However, the vast majority either have no effect or have a negative impact on our health. The best-known cause of mutations is radioactivity. Radioactive rays and particles actually impact the DNA in our cells and physically alter our genes. They mostly go unnoticed or cause deadly diseases, such as cancer, or congenital abnormality in newborns. Mutations are also caused by substances in burned food. The substances enter the cells and damage our genes, which can lead to colon cancer, among other forms of cancer. UV radiation from the sun can also damage our genes and cause diseases, such as skin cancer.

External influences can affect individual genes and disrupt their function, but the majority of our defective genes are inherited from our parents. Each embryo receives half of its genes from the father and half from the mother, resulting in a new human being with some characteristics of each parent. Whether a genetic defect is passed on, is determined randomly, and it may be that some of the children carry the defective gene and others do not.

Each person is the unique product of generations of accumulation and combination of different genetic traits. Some of those traits have negative effects on our health. With the latest technology, it is now finally possible to examine genes and determine personal health risks and strengths. In many cases, taking advantage of this knowledge, and following some precautionary measures, the diseases may be prevented. This is the next step in preventive medicine and a new generation of health care.

Action index

Discuss risks marked in orange or red with your doctor. All other results do not require any further attention assuming there are no current medical conditions.

Effective prevention and early detection of skin cancer

Skin cancer

Although skin cancer is visible on the skin and can theoretically be diagnosed and treated easily, some tumours often develop inconspicuously and in concealed areas, only causing symptoms once they have already spread throughout the body.

There are basically two types of skin cancer:

Light skin cancer: This leads to a cancerous reproduction of light skin cells (basal cells or prickle cells). Although this form of cancer is common, it is usually very treatable and rarely fatal.

The black skin cancer: Black skin cancer, also called melanoma, is rarer and more dangerous. It is caused by a cancerous proliferation of pigment cells, which are usually responsible for a sun tan.

Risk factors

In addition to excessive UV radiation from the sun or a solarium, genetic factors play a significant role in skin cancer progression. Thus, individuals with an increased number of skin blemishes, family history of skin cancer, and skin types that don't tan well and easily develop mild sunburns, are at a particularly high risk.

Prevention and early detection

Protecting yourself from excessive UV radiation with sunscreen is a primary precautionary measure against skin cancer. In addition, the early detection of the disease is considerably important for successful treatment. Usually, skin cancer forms from skin blemishes, which can change visually and possibly lead to discomfort. The blemish will be examined visually by your doctor and, if necessary, also in the laboratory to diagnose possible skin cancer. In many cases, the blemish is then excised, effectively curing the cancer.

Self-examination

Regular self-examination is an essential part of early detection, especially for genetically predisposed individuals and those who have had skin cancer previously. Depending on the level of risk, you should examine your skin for any changes every 3 to 6 months (especially where the blemishes occur). If skin lesions are discovered, they should be discussed with the doctor immediately.

Genes relevant to skin cancer

Several genetic variations have been identified that are known to have an impact on the development of skin cancer. If considering these genetic variations as a whole, they can have a significant impact on the likelihood of developing the disease. The analysis of the relevant genetic variations allowed for the following conclusions:

Genetic traits

LEGEND: rsNCBI = description of examined genetic variation, POLYMORPHISM = form of the genetic variation, GENOTYPE = personal analysis result

Summary of effects

Here is a summary of the impact genetic variations have on your health:

- Your risk of developing malignant melanoma ("black skin cancer") is lower than the population average.
- Your risk of developing non-malignant melanoma ("light skin cancer") is lower than the population average.

Risk of malignant melanoma ("black skin cancer")

Risk of light skin cancer (non-melanoma skin cancer)

Prevention

Since you do not have an increased risk of skin cancer, you will not need any precautionary measures beyond the typical recommendations for early skin cancer detection.

Recommendations for prevention and early detection

The following measures are recommended for you:

- Examine all areas of your skin visually and by palpation once a year.
- Talk to your doctor immediately if you notice changes in the skin or blemishes.
- Use sufficient amounts of sunscreen when outdoors.

Skin Health Sensor

CDK10 - Cyclin dependent kinase 10 (rs258322)

The protein encoded by this gene belongs to the CDK subfamily of the Ser/Thr protein kinase family. This kinase plays a role in cell cycle regulation. Multiple transcript variants encoding different isoforms have been found for this gene. At least three alternatively spliced transcript variants encoding different isoforms have been reported, two of which contain multiple non-AUG translation initiation sites.

RES	Genotype	POP	Possible results
X	C/C	62%	No increased risk of melanoma
	C/T	28%	Increased risk of melanoma (OR: 1.64)
	T/T	10%	Increased risk of melanoma (OR: 2.69)

MTAP - Methylthioadenosine phosphorylase (rs7023329)

Methylthioadenosine Phosphorylase is an enzyme that plays a major role in polyamine biosynthesis and the methionine salvage pathway. The enzyme is deficient in many forms of cancer because the gene and the tumour suppressor p16 gene are co-deleted.

RES	Genotype	POP	Possible results
	A/A	33%	No protection against melanoma
X	A/G	45%	Protection against melanoma (OR: 0.83)
	G/G	22%	Protection against melanoma (OR: 0.69)

MYH7B - Myosin heavy chain 7B (rs1885120)

MYH7B is belongs to the motor domain superfamily. It catalyzes the ATP hydrolysis and interacts with actin. Experiments have shown that MYH7B is not expressed in a large number of melanoma cell lines.

RES	Genotype	POP	Possible results
	G/G	98%	No increased risk of melanoma No increased risk of non-melanoma skin cancer
X	C/G	1%	Increased risk of melanoma (OR: 1.55) Increased risk of non-melanoma skin cancer (OR: 1.46)
	C/C	1%	Increased risk of melanoma (OR: 2.40) Increased risk of non-melanoma skin cancer (OR: 2.13)

Bishop DT et al. Genome-wide association study identifies three loci associated with melanoma risk. Nat Genet. 2009 Aug,41(8):920-5.

NCOA6 - Nuclear receptor coactivator 6 (rs4911442)

Nuclear receptor coactivator 6 is a multifunctional transcription coregulator that can enhance transactivation by other transcription factors and is involved in cell survival, growth and development. The gene is amplified in several human cancers including breast cancer, colon and lung cancers.

RES	Genotype	POP	Possible results
X	A/A	93%	No increased risk of melanoma
	A/G	6%	Increased risk of melanoma (OR: 1.76)
	G/G	1%	Increased risk of melanoma (OR: 2.73)

PARP1 - Poly(ADP-ribose) polymerase 1 (rs3219090)

PARP1 (Poly(ADP-Ribose) Polymerase 1) is an enzyme which modifies various nuclear proteins by poly(ADP-ribosyl)ation. The protein is involved in the regulation of various cellular processes such as differentiation, proliferation and tumour transformation.

RES	Genotype	POP	Possible results
	A/A	30%	Protection against melanoma (OR: 0.74)
	A/G	43%	Protection against melanoma (OR: 0.86)
X	G/G	27%	No protection against melanoma

SLC45A2 - Solute carrier family 45 member 2 (rs16891982)

The SLC45A2 gene (also called MATP) provides instructions for making a protein that mediates melanin synthesis and has been found to play a role in pigmentation. It is also a melanocyte differentiation antigen that is expressed in a high percentage of melanoma cell lines.

RES	Genotype	POP	Possible results
X	G/G	22%	Protection against melanoma (OR: 0.18)
	G/C	11%	Protection against melanoma (OR: 0.42)
	C/C	67%	No protection against melanoma

MC1R - Melanocortin 1 receptor

The MC1R gene provides instructions for making a protein called the melanocortin 1 receptor. The G protein–coupled receptor is located on the surface of melanocytes which produce the pigment melanin through the process of melanogenesis. The MC1R score can be calculated based on the classification of MC1R variants, as implemented by Davies et al.

RES	Genotype	POP	Possible results
X	Score 0	31%	No increased risk of melanoma No increased risk of non-melanoma skin cancer
	Score 1	25%	Increased risk of melanoma (OR: 1.24) Increased risk of non-melanoma skin cancer (OR: 1.41)

ASIP - Agouti signaling protein (rs4911414/rs1015362)

The agouti-signaling protein is encoded by the agouti gene and influences the distribution of black and yellow pigments in the skin and hair. A haplotype (rs4911414 T and rs1015362 G) in the proximity of ASIP is not only associated with pigmentation features, but is also involved in the development of skin cancer.

RES	Haplotype	POP	Possible results
X	-	99%	**No increased risk of melanoma** **No increased risk of non-melanoma skin cancer**
	GG_TT	1%	**Increased risk of melanoma (OR: 1.5)** **Increased risk of non-melanoma skin cancer (OR: 1.45)**

LEGEND: RES = your personal analysis result (marked with an X), GENOTYPE = different variations of the gene (called alleles),
POP = percent of the general population that have this genetic result,
POSSIBLE RESULTS = influence of the genetic variation.

Certifications

Our laboratory is one of the most modern and automated laboratories in Europe and has numerous certifications and quality assurance systems that meet, and even exceed, international standards. The various areas of business are certified separately to the highest standards.

Laboratory diagnostics, manufacturing & sales

Quality management system in accordance with ISO 9001:2015

qualityaustria
SYSTEM CERTIFIED
ISO 9001:2015 No.14365/0

Licensed for medical genetics

Approved by the Federal Ministry of Health, Austria

BUNDESMINISTERIUM FÜR GESUNDHEIT

Cosmetic/genetic diagnostics and cosmetics manufacturing

Good manufacturing practice (GMP) in accordance with ISO 22716:2007

qualityaustria
SYSTEM CERTIFIED
EN ISO 22716:2007 No.00010/0

Food supplement manufacturing

Management system for food safety in accordance with ISO 22000:2018

qualityaustria
SYSTEM CERTIFIED
ISO 22000:2018 No.00521/0

Customer Service

Questions or comments about our service?

Our customer service team is happy to help with any enquiries or problems. You can contact us in the following ways:

- Phone +41 (0) 41 525 100.1
- office.ch@progenom.com

Our team is looking forward to your call. Customer satisfaction is our first priority. If you are not fully satisfied with our service, please let us know. We will do our best to help find a satisfactory solution to your problem.

Technical details

Order number
DEMO_DS

Date of birth
01/01/1990

Established analysis methods
qRT-PCR, DNA sequencing, fragment length analysis, CNV assay, GC-MS, Immunocap ISAC, Cytolisa

Report generated
19/03/2021 17:59:06

Product codes
M7SKI

Current version
V538

Ordering company
ProGenom GmbH
Riedstrasse 1
6343 Rotkreuz
